MICRO COMPUTER AIDED ANALYSIS, DESIGN AND INDUSTRILIZATION CF STRUCTURES

BY

DR. IBRAHIM MAHFOUZ MCHAMED IBRAHIM ASSOCIATE PROFESSOR, ZAGAZIG UNIVERSITY BANHA BRANCH, DEPT. OF CIVIL ENGINEERING SHOUBRAH, CAIRO, EGYPT

In this work, a series of articles is presented with the objective of introducing and demonstrating the great potential of the use of computers in the analysis, and design of structures, as well as, in achieving automatic optimum minimum weight, or minimum cost design for the industrilized structural components fabricated in large quantities.

The first group of articles is devoted to present the use of micro computers in enhancing and simplifying structural engineering work through the development of design aid tables for certain types of structural elements commonly used by engineers. Sample programs are presented for the design and the development of design aid tables for reinforced concrete structural elements. The first group of articles is also concerned with the introduction of the computer aided analysis of structures. In order that the important idea of the utilization matrix formulation in structural analysis may be set forth with a minimum of confusion, the development of the matrix formulation and the computer program for the analysis of beams by the equation of three movements are presented.

The second group of articles is devoted to introducing the computer oriented structural analysis techniques, namely, the finite element displacement method of structural analysis. The first topic covers a brief history of the development of the finite element method, fcllowed by a second article for the presentation and derivation of the formulation of the finite element displacement analysis of structures such as, plane and space trusses and frames. In addition, computer programes are presented and applied to the analysis of these types of structures. To end the second group articles, the criteria for the evaluation of commercial software are presented and applied to evaluate a sample of commercially available programs in the various categories of structural analysis and designs.

Finally, the third group of articles is devoted to industrilization of structures. In order to illustrate the structural synthesis concept, or in other words the automated optimum design of a structural system, a case study of the automated minimum cost design of prefabricated prestressed concrete beams is presented.

خاسبات الالكترونية مسفيرة واستخدامها الي المجالات المندسية

دكتور / ابراهيم محمد ابراهيم استاذ مساعد الهندســة الانشائيــة بكليـــة الهندســـة – شــــرا

بدأ استخدام الحامبات الالكترونية الصغيرة في الظهور كعنصر أساسي في جراء الأعمال الإدارية والمالية والهندسية بوجه عام ، وأعمال الهندسة الانشائية بغروعها التصميمية وانتنفيدية والتصنيعية بوجه خاص، وذلك كنتيجة للانخفاض الكبير والمستمر في أمعار شرائها حيث أصبحت لحاسبات الالكترونية في حدود امكانيات كافة الميتعت وكثير من الأفراد . وبناء عليه وجب على المهندسين السارسين وكذلك على الهيئات العلمية والجامعات أخذَ هذا التطور الكبير في الاعتبار مأخذا جديا وسربعا حيث أنه يمكن القول ان • ثورة • استخدامات الحاسبات الالكترونية في المجالات الهندسية قد بدأت علميا بالفعل ، وأنه من المتوقع أن تشمل هذه و الثورة ؛ منطقتنا في القريب العاجل بحيث يمكن القور أنه من غير المستبعد أن الأشخاص والهيئات التي سوف تتجاهل هذه ه الثورة ، سوف تصل إن مرحلة من الجمود وعدم الفاعلية في مجالات الممارسة الهندسية .

ان استخدام الحاسبات الالكترونية في مجالات الهندسة الانشائية مثلا سوف يتيح للمهندم المصمم التركيز على اختيار أحسن وأنسب نوعية للمنشأ ، وعلى عمل الدراسات لموصول إلى النظم الانشائية الأكثر اقتصاداً ، وكذلك على اعطاء الحلول المرادفة وذلك بدقة وسهولة وسرعة تاركا اجراء العمليات الحساية المقدة المتهلكة للوقت وللطاقة البشزية للحاسب الالكترولي مستخدما البرامج الهندسية انتخبرة والموثوق منها والتي تلامم طبيعة ونوعية النشأ المطلوب تصميمه ، هذ بالإضافة إلى السهولة في اجراء التعديلات في التصميم الانشائي التي تتلام مع المطلبات الهندسية الأخوى مثل المطلبات المعمارية

مقدمية :

مون الله تعالى وايمانا من مجلة ، عالم البناء ، بدورها الرائد في نشر النقافة المعمارية واهتسية ، تقوم المجلة ابتداء من هذا المدد بنشر ملسلة من المقالات والموضوعات الهندمية التي يعدها مركز الحاسب الالكترولى بمركز السرمات التخطيطية والمعمارية تحت اشراف السرعات التخطيطية والمعمارية تحت اشراف وستركز هذه المقالات على تفطية جوانب المريف بالحاسبات الالكترونية وعناصرها

-

the stilled atom a.c. m

Intering and the later

والميكانيكية ... الخ سواء في المراحل الأولية في التصميم أو لأى تعديلات طارئة .

ان تعميم استخدام الحاسبات الالكترونية سوف يتيح للمهندس عمل تصميمات ذات دقة عالية وذلك باستخدام ادق النظريات في كتابة البرامج للحاسب الاكتروتي بدون الحاجة إلى عمل الافتراضات التقريبية حى تتلامم النظريات مع الحل اليدوي، هذ بالإصابة إلى الغاء أو التقليل من احتالات الأخطاء الشرية المكن حدوثها في اثناء اجراء العمليات الحسابية يدويا هذا مع سهولة أخذ كافة التحميلات والاحتالات التصميمية في الاعتبار بالاضافة إلى سهولة مرجعة التصميمات، وكتيجة

Ty,

وأسلوب تشفيلها، كما ستركز أبضا على أعطاء نماذج لأساليب استخدام الحاسب الالكترولى لي التصميم الانشاقي، كما سيتم اعطاء جداول تصميمات للمشتات المتلفة اعدت بواسطة الحاسب الالكترولى، وتساعد هذه الجداول على تبسيط أعمال التصميم الانشائي وتهم كافة المهندسين والباحين والدارسين في مجالات العمارة والهندسة الاشائية.

وبالله التوفيسق ...

لذلك يستطيع المهندس اتمام عمله وهو على ثقة كبيرة من دقة تصميماته .

ان استخدام الحاسبات الالكترونية سوف يغتج المجالات لحل وتصميح نوعيات من المنشئات كان من الصعب أو من المستحيل يلويا حلها لعدم امكانية والتكلفة المقبوة وبطريقة عملية يمكن اتمامها في فترة زمنية معقولة . هذا بالإضافة إلى فتح المجالات لتحسين نظم تنفيذ استاريع وحصوصا للمشاريع الكبرة المعقدة والتشابكة . ان استخدام الحاسبات الالكترونية في مجالات تصنيع الماني سوف يتبح للمصمم المنتج المكانية الرصون و اتوماتيكيا و إلى تصيمات للوحدة

-تفاصيل في أجزاء من منشأت معدنية مصممه ومرسومة بواسطة الحاسب الالكتروني .

الواحدة بحيث يكون وزنها أو تكلفة انتاجها أقل ما يمكن MINIMUM COST AND MIIMUM) (MINIMUM COST AND MIIMUM) وهذا مع استفاء كافة المتطلبات الانشائية وذلك باستخدام نظرية الحد الأمثل OPTIMIZATION وهذا سوف يكون له كبير الأثر في الاستخدام الأمثل للمواد المختلفة المستخدمة . وفي

تقليل الفاقد في المواد نتيجة عوامل عـم الوثوق مما ي عى اضافة عامل كبير للأمان عند التصميم ، وهذا بدوره ينعكس على الانتاجية والتكنفة التفيذية للمسشأ وخصوصا ان الاجزاء المصنعة المختلفة تنتج بكيات ك ، والوفر في تكلفة انتاج وتنفيذ الوحدة الوحدة مهما كان بسيطا ، وسوف يكون تأثيره على التكلفة الاسالية للمنشأ أو لمجموعة المنشئات كبيرا خصوصا إذ ضعنا في الاعتبار ان تصنيع البناء يرتبط أساسا بالانتاج المكثف من نفس الوحدة النمطية .

العادى، وذلك نظرا لملاحمة هذه النظريات لاستخدامات الحاسب الالكترونى وكذلك من المتوقع ان تتوارى بعض النظويات المألوفة الأخرى في الظل وذلك لعدم سهولة برمجتها . وهذا التطوير والتغيير سوف يكون له أكبر الأثر على نظم التعليم الهندسي العالمي أو المحلي .

وختاما أود أن أقول أنه منذ فترة ليست ببعيدة ترك المهندسون المساطر الحاسبة التي اعتادوا وتمرسوا عليها في الماضي واستخدموا الحاسبات الالكترونية وخصوصا أن بعضها أصبح في حجم الحاسبات

ومكتوب جدوال تسليمها بواسطة الحاسب الإكروني .

اليدوية الشائع استخدامها الآن مع الفارق الكبير في المقدرة الحسابية، حتى تستطيع أن نساير هذه د الثورة، في مجالات الهندسة الختلفة ونبدأ التفكير في حل المشكلات الهندسية بعقلية ونظم الحاسب الالكترولي .

الدكتور/ابراهيم محفوظ محمد ابراهيم استاذ مساعد المندسة الانشائيـــة بكليــة المندســــة بشـــبرا

يمثــل تحديد مساحات وأوزان حديد التسليح المستخدم فى الخرسائات مسألة أسـسية سواء بالنسبة للمصمم بالـمكتب أو المنفذ بالموقع أو لمعد تحليل العطاء لتقديم مشاقصة لمشـروع ما • ونسجل فى هذا المقال برنامجـا مبســطا للحاسـب الآلى مكتوبا بلغة ال FORTRAN والخاص بعمل جداول لحساب مســاحات وأوزان حديد التسليح لاقطارهـا المختلفة المستخدمة محليا أو عالميا ، بهـد ف اعط ء المهندس مقدمة لكيفيةكتابة برنامج للحاسب الآلى فى أبسط صوره •

شـكل رقم (١) يببن المسار البيائى FLOW CHART الخاص بالبرنامج المبين فى شكل رقم (٢) والخاص بحساب أوزان حديد التسليب لمتراوح من ١ الى ٥٠ لاقطار الحديد المختلفة (٢٨ حتى ٣٠ مم) ولعدد أسياخ يتراوح من ١ الى ٥٠ والبرنامج ممكن تكرار تنفيذه عدة مرات على حسب اعداد الجداول المطلوبة فـــى حالة الرغبة فى طباعته آليا بواسطة الحاسب الآلى ٥ ومن الملاحية أن هــــذا اليرنامج ممكن ممكن معكار متخدامه لعمل جداول خسابات المساحات الاجمالية لحديد البرنامج ممكن معين استخدامه لعمل جداول حسابات المساحات الاجمالية لحديد من السليح بعد تغيير العنوان فى سطر رقم ١٢ وعمل تعديل بحذف وزن وحدة الحجوم من السطر رقم ٢٣ ٥ ويوضح الشكلان رقم (٣) ، (٤) الجداول الناتجة عن تنغيات

COMPUTER AIDED DEVELOPMENT OF DESIGN AID TABLES FOR REINFORCED CONCRETE STRUCTURES

BY

DR. IBRAHIM MAHFOUZ M. IBRAHIM ASSOCIATE PROFESSORS, ZAGAZIG UNIM. BANHA BRANCH, CIVIL ENGINEERING DEPT. EGYPT

The objective of this work is to present a fortran computer program for the development of design aid tables for reinforced concrete sections subjected to bending moments. The tables can be used to greatly simp plify the design of a variety of reinforced concrete structural elements such as, beams having rectangular, T or L sections, slabs, flat slabs, footings ... etc... The computer program is based on the " JLTIMATE " strength design method of the ACI 318-83 building code requirements for reinforced concrete.

In the " ULTIMATE " strength design method, the depth of the reinforced concrete section, d can be expressed in terms of the " ULTIMATE MOMENT " M, and the width, b as follows:

 $d = \sqrt{\frac{M_u}{4 B R_n}}$ (1)

where

 $R_n = F_y [f - f^2 F_y / [1.7 F_c]]$ (2)

(2b)

and β is the percentage of steel = A_s/bd

 F_v = Yield strength of the reinforcing steel

 F_{C}^{\prime} = Compressive strength of concrete cylinder after 28 days.

It is pointed out that the design aid tables give the values of R_n for various percentages of steel, S, for different values of F_c and F_y . In the preceding Equation, 1, fis the strength reduction factor and is equal to 0.9 for flexure. Note that the strength reduction factor accounts for uncertainties in design computations and relative importance of various types of members, and provides for the possiblity that small address variations in material strengths, workmanship, and dimensions, while individually within acceptable tolerances and limits, may combine to result in understrength. The required moment strength, M, or, the factored moment, is computed as:-

$$M_{u} = LF_{DL} M_{d} + LF_{LL} M_{L}$$
(3)

where, M_d and M_L are the moments due to service dead and live loads, respectively, and, LF_{DL} and LF_{LL} are the load factors for dead loads and live loads, which provide for excess load effects from such possible sources as overloads and simplified assumptions in structural analysis. Recommended load factors for the middle eastern region can be taken equal to, $LF_{DL} = 1.5$ and $LF_{LL} = 1.8$

The flow chart of the computer program and the listing of the program are shown in figures 1 and 2, respectively. Sample output design aid tables are presented in the tables, for various combinations of F_c^i and F_y . It should be noted that the program is independent of the qualities and units of both concrete and steel and can be used in the cases where the quality of concrete is represented by its cube strength.

n REPORT NO. - DTSUTIL ICCF LIBRARY FILE MAINTENANCE 13.47 DATE 03/20/84 PAGE 2COMMENTS 0 HEAD 0 2 1) TABLES FOR THE DESIGN OF R.C. 2 3 SECTIONS SUBJECTED TO BENDING MOMENT 2 0 2 D = SQRT (HULT / Q RN B) 6 ROW = AS / (B D) 2 23 WHERE 4 = 0.9 3 MULT = ULTIMATE MOMENT 5) D = DEPTH OF THE BEAM B = WIDTH OF THE BEAM u) AS = AREA DF STEEL a FY = YIELD STRENGTH OF STEEL FC1 = COMPRESSIVE STRENGTH OF CONCRETE 7 CYLINDER AFTER 28 DAYS

COMPUTER AIGED ANALYSIS OF CONTINUOUS BEAMS BY THE EQUATION OF THREE MOMENTS

BY

DR. IBRAHIM MAHFOUZ M. IBRAHIM ASSOCIATE PROFESSOR, ZAGAZIG UNIV. BANHA BRANCH, DEPT. OF CIVIL ENG. SHOUBRA, EGYPT. 5

In this work, a Fortran computer program for the analysis of continuous beams by using the Equation of Three Moments is presented. The beams are assumed to have different stiffnesses and subjected to different combinations of the types of loads as shown in fig. 1.

In order to facilitate the development of the computer program, the three moments equations are represented by the following matrix,

$$\begin{bmatrix} F \\ NXN \end{bmatrix} = \begin{cases} R \\ N \end{cases}$$
(1)

where

{M}- a vector containing the connecting moments at the intermediate supports.

{R}- a vector containing the elastic reactions resulting from the externally applied loads.

N - the degree of indeterminacy of the structure

F

[F] - flexibility matrix. The various elements of the matrix are as follows:-

$$F_{ii}=2\begin{bmatrix} L_{i} & L_{j} & i=1,2,...,N \\ \hline I & I & J \\ \hline I & i & j & j \end{bmatrix} (2-a)$$

Fij⁼Fji (2-b)

$$ij^{=} \frac{L_j}{E_j I_j}$$
(2¬r)

`and all the other elements an equal to zoro.

The flow chart and the listing cf the computer program are shown in Figures 2 and 3, respectively. Sample outputs are presented in Figure 4.

A BRIEF HISTORY OF THE DEVELOPMENT OF COMPUTER ORIENTED STRUCTURAL ANYLYSIS TECHNIQLES

6

BY

DR. IBRAHIM MAHFCUZ M. IBRAHIM ASSOCIATE PROFESSOR, ZAGAZIG, UNIV. BANHA BRANCH, DEFT. OF CIVIL ENG. SHOUBRA, EGYPT.

Up to recently, structural engineers have to solve even the most complex problems with only a slide rules or hand calculators. As a result, long hours have been usually spent im performing the structural analysis. Often a grossly simplified model of the actual structure had to be used and the number of load conditions kept to a minimum. In addition, structural engineering judgement rather than reliable analytical data had to be used to an exceptional degree in specifying structural requirements, especially at the preliminary formative design stages.

This unsatisfactory state of affairs underwent a drastic change with the advent of the high-speed electronic computers. In seeking to exploit fully the advantages offered by electronic computers, It soon became evident that the existing crude idealizations used in approximating actual structures might be replaced by greatly refined models. This, in turn, stimulated the development of the <u>matrik methods of structural analysis</u> which first began appearing in the early 1950s. It was recognized that when fundamental structural principles are applied to the calculation of deformations and internal forces in structure tuilt up from many component parts, matrices furnish the most convenient mathematical language for expressing the theory. Furthermore, the solution of the equations expressing the theory can be best achieved as a sequence of matrix numerical calculations. The computer is ideally suited to carrying cut these matrix operations.

THE MATRIX FORCE METHOD.

As might have been guessed, the first steps at providing solutions followed traditional lines, which had grown out of the theory of elasticity and followed the general approach of calculating internal stresse by using fundamental conditions of equilibrium of forces and continuity of displacements. Deformations could then be obtained by a second, subsequent calculation. This procedure is known as the redundant force method. In recent years it has been often called the force method. In the early 1950s, force method was formulated in general matrix terms and, in addition, introduced the use of the electronic computer for obtaining the desired solutions. Subsequently, it was realized that displacements, rather that internal forces, could be chosen as the primary unknowns of the structural problem. This alternate choice of unknowns ther brought the stiffness matrix intothe formulation. In early works the stiffness matrix was not calculated directly as in present-day finite element work, but rather was obtained by inverting the then more familiar; Flexibility matrix, Hence, the stiffness method was considered as an alternate choice for solving the equations generated from the force method point of view.

THE MATRIX STIFFNESS METHOD " THE DISPLACEMENT METHOD "

In spite of the foregoing progress in developing the force method, it became clear in the first half of the 1950s that the ultimate solution might well have to be sought in other directions. This was due to the fact that the force method was unable to take full advantage of the computer's capability and that the force method burdens the user with extensive data preparation (e.g. setting up and inputing the equilibrium equations). As a result, the stiffness method and subsequently the finite element or discrete element methods which are computer oriented techniques requiring minimum data preparation were developed. The stiffness and finite element methods have been developed to the point where they can be applied to almost any class of engineering structures. A partial list of structural problems which can be investigated, using these matrix procedures, is as follows,

1

- 1- Two-diminsional and space trusses and frameworks.
- 2- Thin plates and slabs cf arbitrary shapes
- 3- Shell structures of arbitrary geometry
- 4- Composite structures, including combinations of plates, curved-shell elements, and truss and beam elements,

5- Solid bodies of irregular shapes.

INTRODUCTION TO THE FINIT ELEMENT DISPLACEMENT METHOD OF STRUCTURAL ANALYSIS.

BY

DR. IBRAHIM MAHFOUZ M. IBRAHIM ASSOCIATE PROFESSOR, ZAGAZIG UNIV. BANHA BRANCH, DEPT. OF CIVIL ENGINEERING EGYPT

The basic idea of the finite element methods of structural analy-i sis is to replace an actual complex structural system by a set of simpler structural elements. In formulating the simplified or idealized structural system, use is made of the so-called finite element method. If the simpler system can be solved, and the resulting solution represents the true solution with satisfactory accuracy, the finite element method would have obviously served a useful purpose.

From the preceding statement it can be realized the finite element method of analysis requires the derivation of the formulation of the basic elements commonly employed structural engineering practice. These element are as follows: -

1- Truss Element

2- Frame work element

3- In-plane plate element

4- Plate bending element

5- Axisymmetric thin & shell element

6- Curved thin shell

7- Solid elements

8- Axisymmetric soild elements

The various types of element are shown in figure 1.

In this work, and in order that important ideas and method procedures may be set forth with a minimum of confusion, the discussion will be limited to the direct stiffness " Displacement ', analysis of simple types of structural systems as listed as items 1 and 2. This includes, but not limited to, the analysis of plane and space trusses, frames and grid work. In the displacement method of structural analysis, the formulations of the element (e,g, truss element, beam element, ... etc), are first derived with respect to the local coordinate system \widetilde{X} , \widetilde{Y} and \widetilde{Z} of the element. It will be shown for the various types of elements considered herein that the forces and moments at the two ends of the beam element, $\{\widetilde{P}_e\}$, are related to the end displacements and the end rotations of the element, $\{\widetilde{X}_e\}$, by the following relation.

$$\begin{bmatrix} \tilde{K} \\ e \end{bmatrix} \left\{ \begin{array}{c} \tilde{X} \\ e \end{array} \right\} = \left\{ \begin{array}{c} \tilde{P} \\ e \end{array} \right\}$$
(1)

where K_e is the element stiffness matrix in the local coordinate system. In order that the geometric admissibility conditions of the principal of minimum total potential energy (i.e. compatibility of deformations and rotations) can be imposed at the common ends of the rig-dly connected elements, the end displacements must be transformed from the local coordinate system of the individual element to a single reference coordinate system for the structure, X,Y,Z. The relation between the displacements and rotations in the reference coordinate system, $\{X_e\}$ and those in the local coordinate system $\{\widetilde{X}_e\}$ can be expressed as: -

$$\left\{\widetilde{X}_{e}\right\} = \left[T\right] \left\{X_{e}\right\}$$
(2)

where [T] is the transformation matrix. Similarly the relation between the end forces and moments in the reference coorcinate system $\{P_e\}$ and those in the local coordinate system $\{\widetilde{P}_e\}$ can be written in the form.

$$\left\{\widetilde{P}_{e}\right\} = \left[T\right] \left\{P_{e}\right\}$$
(3)

substilution of the relations 2 and 3 into Equations (1), yields.

$$\begin{bmatrix} K \\ e \end{bmatrix} \begin{cases} X \\ e \end{cases} = \begin{cases} P \\ e \end{cases}$$
(4)

where $\begin{bmatrix} K_e \end{bmatrix}$ is the element stiffness matrix in the reference coordinate system given by,

$$\begin{bmatrix} \mathsf{K} \\ \mathsf{e} \end{bmatrix} = \begin{bmatrix} \mathsf{T} \end{bmatrix} \begin{bmatrix} \widetilde{\mathsf{K}} \\ \mathsf{e} \end{bmatrix} \begin{bmatrix} \mathsf{T} \end{bmatrix}$$
(5)

by imposing the geometric admissibility conditions between the various beams, as well as, the supporting conditions, the following relation can be written,

 $\begin{bmatrix} K \end{bmatrix} \left\{ X \right\} = \left\{ P \right\}$ (6)

Where [K] is the overall stiffness matrix associated with the independent degrees of freedom residing in $\{X\}$. Solution of the preceding equation (Eq. 6), yields the displacement $\{X\}$. Subsequently, the forces and moments at the two ends of each beam can be obtained.

The flow chart of a general purpose computer program using the displacement method of structural analysis described herein and developed by the writer is shown in Fig. 1.

In the articles that will follow the displacement method formulations, that is, stiffness and transformation matrix for specific structural systems are presented. The cases considered are as follows: -

- 1- Plane Trusses
- 2- Space Trusses
- 3- Plane Frames
- 4- Shear Walls
- 5- Space Frames
- 6- Structural grid systems
 - (i.e. paneled beams)

(b) Plano stress

(c) Solid elements

(e) Flat plate bending

(f) Axisymmetric thin shell

(g) Curved thin shells

I- ANALYSIS OF TRUSS STRUCTURES BY THE DISPLACEMENT METHOD

BY

DR. IBRAHIM MAHFOUZ M. IBRAHIM ASSOCIATE PROFESSOR; ZAGAZIG UNIV. BANHA BRANCH, DEPT. OF CIVIL ENG. EGYPT 8

In this article, the displacement method of analysis of plane and space truss structures is presented. Consider the truss element shown in Figure 1. The positive directions of the axial forces and axial displacements of the two ends of the element in the local coordinate system $\widetilde{X}, \widetilde{Y}$ and \widetilde{Z} of the element are assumed to be in the directions shown in Fig. 1.

The element stiffness matrix can be derived by applying the principal of the minimum total potential energy. Alternatively the elements of the stiffness matrix can be obtained using standard structural engineering approach. The resulting element stiffness matrix in the local coordinate system $\lceil \widetilde{K_e} \rceil$ can be expressed as: -

AE

The relation between the end displacement of an element in the local and the global coordinate system shown in Fig. 2, can be represented by

{X_e} (2b)

Note that for two dimensional truss structures in the x,z plane,

$$V_1 = V_2 = 0$$
, also, cas $\theta_v = 0$

IMPLEMENTATION

 $\left\{ \widetilde{x}_{e} \right\}$

The input data for the computer program out-lined in the preceding article using the displacement method of structural analysis, are as follows for the cases of truss structures.

- a) Title
- b) Number of truss elements, degrees of freedom and loading conditions.
- c) Joint loads for the various loading conditions.
- d) Degrees of freedom and restrained joints
- e) Cross-sectional area and the X, Y, Z coordinates of the two ends of each truss element.

Sample output of the program are presented in Figures 3-4 for the cases of plane and in Figure 5 for a space truss.

II- ANALYSIS OF PLANE AND SPACE FRAMES BY THE DISPLACEMENT METHOD

BY

DR. IBRAHIM MAHFOUZ M. IBRAHIM ASSOCIATE PROFESSOR, ZAGAZIG UNIV. BANHA BRANCH, DEPT. OF CIVIL ENG. EGYPT

In this article, the displacement method is extended to the analysis of plane and space frame structures.

A- PLANE FRAME STRUCTURE

In this section the analysis of two-dimensional frames and shear wall structural systems by the displacement method is presented. It is pointed out thatformulation presented herein is general and include in addition to the flexural and axial deformations of the element, the effect of shear deformation which is quiet significant in the cases of shear wall structural systems. Consider the beam (i.e. frame work) element shown in Fig. 1. The positive directions of the forces and moments, as well as, the displacements and rotations of the two ends of the beam element in the local coordinate system of the element are assumed to be in the directions shown in Fig. 1.

The element stiffness matrix $[\tilde{K}_{e}]$ derived using either the principal of minimum total potential energy, or standard structural engineering principals, which includes the effects of axial, flexural and shear deformation, can be expressed as shown in Equation 1a:-

Note that the coefficient \propto , accounts for the shear deformation in the deep beam element that is, the wall element and vanishes for standard slender beam element.

The transformation matrix derived by imposing the compatibility of deformations between the displacements and rotations in the local and the reference coordinate systems, can be expressed as given in relation (2**b**),

(Ũ1 $\widetilde{F_1}$ 0 AE L 0 К1,1 0 0 . Vī W 12 EI_y 6 EIy 0 K_{2,3} - K_{2,2} (1+x) L³ (1+a)L² \widetilde{M}_{1} (2-9) EIy $\widetilde{\theta}_{y_1}$ - K_{2,3} (4+9) EIy 0 (1+a) L L = 0 $\widetilde{F}_{\mathbf{2}}$ Ũ2 0 к 1,1 Ĩ, $\widetilde{\mathtt{W}}_2$ (SYMMETRICAL) -K_{2,3} K2,2 ™2) 12 E I_y θ_{y2}) к_{3,3} $\propto = \frac{1}{G A_r L^2}$ $\left\{ \tilde{X}_{e}\right\}$ $= \left\{ \widetilde{P}_{e} \right\}$ $\left[\widetilde{K}_{e}\right]$

4

......

B- SPACE FRAME STRUCTURES

The discussion in this section is focused on the analysis of three dimensional frame structural systems by the displacement method. The formulation presented herein can be used in the analysis of a wide variety of three dimensional structural systems, such as paneled beam floors, general space frame structures, raft foundations idealized as structural grid system, and three dimensional shear wall core systems.

The element stiffness matrix [Ke] of a three dimensional beam element (Fig.2) in the local coordinate system which includes the effects of axial, torsional, unsymetrical flexural and shear deformations, can be expressed as shown in Equation 3a. The relation between the end displacements of a three dimensional beam element in the local and the reference (global) coordinate systems can be expressed by the matrix relation 4a.

ily.

where

 $1 = \cos \theta$ $i \qquad x$ $m = \cos \theta$ $i \qquad y$ $n = \cos \theta$ $i \qquad z$

i = 1,2,3, for the $\tilde{x},\tilde{y},\tilde{z}$, respectively (5)

The input data for the computer program developed by the writer and outlined in a preceding article using the displacement method are as follows, for the various cases of two and three dimensional frame structures.

- 1. Titles and drawing of the structure.
- 2. Elastic properties of the materials.
- 3. Number of beams and number of loading conditions.
- Data for each individual beam element, as follows: a- cross-sectional cimensions.
 - b- x,y and z coordinates of the two ends of the elements. Alternatively, length of the beam element and the angle of orientation with respect to the reference coordinate axes.
 - c- Types of connections at the two ends of the elements including supporting conditions.
 - d- Types, magnitudes and locations of the loads, for all the loading conditions considered

sample outputs for two dimensional frame, paneled frame, paneled beam floor are presented in figures 2, 3 and 4 respectively.

CRITERIA FOR THE EVALUATION OF COMPUTER SOFTWARE

The use of computers in many engineering opplications has grown rapidly, especially with the recent steadily decreasing cost of computer in general and micro computers in particular.

Once an engineer makes the initial decision to use computer aids for a given task, many subsequent decisions become necessary. A decision must be made as to whether or not to use the available software, or to develop one's own programs. This decision must be based upon whether or not there exists software which satisfies the engineer's needs in terms of analytical or design capability and whether the software is not only available, but also economical to buy and to use. Assuming that an Individual has decided to use commercial software, and has been successful in locating several programs which satisfy the engineer's need, how does he then decide which program to use? The decision to use one program instead of another can often be rationalized by examining the programs with specific evaluation criteria in mind. Such criteria can be summarized as follows-

Compatibility between the software and the type of computer in use.

- 2- Documentation.
- 3- Input.
- 4-Solution.
- 5- Output.

1- COMPATIBILITY

Before purchasing schware, one must make sure that the software under consideration is compatible with the type of computer in use, in terms of the operating system (e.g. Dos, UCSD. Cp.M., ...etc), the language (e.g. Basic, FORTRAN, Pascal, ...etc), and that the computer has the memory / storage capacities required to support the software.

2- DOCUMENTATION

The effectiveness of the user's manual, and other documentation n preparing a user to deal with a problem and to

BY Dr IBRAHIM MOHAMMED IBRAHIM ZAGAZIG UNIVERSITY BANHA BRANCH DEPARTMENT OF CIVIL ENGINEERING

> understand the output, is one of the fun damental downfails of some otherwise very useful programs. Since this is such an important problem, it requires the consideration of severa sub-criteria.

2-a Explains Methods

The level at which the documentatio outlines the techniques and the method c design used in the program varies greatly among commercially available programs. Thus, when little information cvailable about how a design is produced, the engineer must be wary of the results obtained.

2-b Data Preparation Aid

As a bare minimum, the documentation for a program should clearly explain ho to prepare the input data for a program Since it has been found, time and again, that it is in the preparation of data that a

treat deal of engineers' efforts are soended.

2-c Output Interpretation

The manual should help the user undersand the output both in case of successful and unsuccessful sun's. There is little that is more frustrating than having a run return with an abunciance of error messages and no real explanation of the problem.

2-d Honesty

There is often a gap between the claims of the documentation, and the real requirements and **capabilities** of the program. This difference may occur because the developer exaggerated the abilities of his program, or because, somewhere along the line a portion of a program became nonfuctional.

3- Input

The form of the input requirements can nave some importance in making the program eas, to use. Also, the ability of a orogram to correct simple errors in input data, and to provide optional default volues for common data is a boon to the user, and parential timesaver. In addition, much time is often spent on generating input which could otherwise, be more efficiently used. The advantages, in terms of time sovec. of a program with the ability to abbreviate the input data by having some dota generated automatically, are substantial.

4- Solution

It is important to assess programs (Softwore), in terms of the analysis and / or design produced by the programs. The level of carifdence which an engineer can have in an automatic design, and the ease with which an engineer exercises direct control over the design, are both factors which bear directly on how useful a specific program is to an engineer. This criterion also divides into two important sub-criteria.

4-A Control

An engineer does not use computer aids for analysis and / or design to avoid becoming involved in the analysis and ' ar design. Rather, most engineers would not feel comfortable using an automatic design procedure unless some control could be exercised over the design produced. The designer will at least war to specify such things as the design code to be invoked.

4-B Quality

In general terms, one should identify the degree to which the output may be considered as a final design, with consideration given to reliability of design values; satisfaction of code requirements; conformity to the most up to date design philosophy; economy of design and the presentation of alternative designs.

5- Output

The effectiveness of the program ou put in communicating the information generated by the program, in a manner useful to the engineer, must receive due consideration. In selecting a program for use, It is worthwhile to scrutinize the output of the program for clarity and organization.

The technique presented hereinnas seen used to evaluate a sampling of commercially available programs in various cotegories of structural analysis and design. The results of the evaluation are summarized in the tables.

Sealution Code Good, Grair, O Poor.

SYNOPSIS: SUBJECT OF THE ISSUE:-

«An Urban Study of Zamaiek District», It a Study points out to the necessity of putling building regulations for the area in proter to preserve its character. The study was conducted by a research learn from me Urban Planning Organization and nesented by arch. Karnal S. Shouhalb.

FERSONALITY OF THE ISSUE:-

It is Prof. Youssef Hassan Shalik, prof. of c philectural design at Colip University, where he started his academic carreer in #42 and uptill now. He received his M.A. cagree in architecture in 1953 from Illinois Lniversity, U.S.A. Prof. Y.H. Shafik participated in the design and p anning of many architectural and urban p anning projects in Egypt and abroad through his own consultancy office.

TECHNICAL ARCTICLE:

+ •Traditional Housing Design in Arab Countries», written by arch. Samlr Abulac. The material presented in this study is t osed on some comparative approaches cealing with the following topics: ecolog ca analysis of human settlements, chalysis of traditional courty and designs, analysis of traditional courtmand housing models, and some examples of contemporary development and disructions.

■ ≪oranic Notions: Function and Beauty Architectural and Urban Design*, written by Dr Hazem Ibrahim.

PROJECTS OF THE ISSUE:

+ Mixed Development at Cidhams Walk, Covent Garden: design team, D. Ball, M. D'connor, J. Watts, S. Groak. The original crel was issued by GLC in 1974 for a mixed use development. The project which lies on an area of D.E ha. includes H02 dwellings at a density of 472 P/ha, and 5000m2 of non-housing in the form of shops, workshops, and community uses.

Urban Housing Projects in Algeria: arch. Abdelrahman El-Minlawy, An Illustration of "we urban housing projects in Algeria, In Eiskia and M'isala.

+ Private House at Jerusalem: architect Mcsrie Safadie. The project is a redeveimpment of the ruin of an old house in Yafa.

AUTOMATED MINIMUM COST DESIGN OF PREFABRICATED PRE-STRESSED CONCRETE BEAMS

Dr. I.M. Ibrahim Associate Professor Faculty of Engineering Zagazig University Shobra, Cairo Egypt Dr. G.R. Monforton Professor and Head Dept. of C vil Engineering University of Windsor Windsor, Cntario Canada

Cne of the main problems of structural designers is to select the best design for a certain structure which satisfies both structural and economical requirements, especially for prefabricated structures where the elements of the structures are usually constructed in large numbers. The objective of this Work is to present a structural synthesis capability to find the optimum design of prefabricated prestressed concrete beams of various shapes automatically. The present structural synthesis

concept is an inequality constrained minimization approach which is based on a number of considerations, namely, a set of design variables, an objective function, a set of constraints and a powerful mathematical programming procedure. The design variables are the independent cross-sectional dimensions of the concrete, the prestressing force, the area of prestressing steel in each row and their distances from the bottom fiber of the beam, as shown in Fig.1. The goal of the structural synthesis concept is to select these variables such that an acceptable minimum cost design is obtained. The objective function, C(V) which reflects the cost of the prestressed concrete beam in terms of the design variables and provides the basis of choice between alternative acceptable design, is taken as follows:

 $C(V) = C_{c} A_{c} + C_{g} A_{g} + C_{f} P_{f}$ (1)

where A_c and A_s are the areas of concrete and prestressing steel, respectively: C_c , C_s and C_f are the cost of concrete including the cost of transportation, cost of steel and forming, respectively. F_f is the perimeter of the cross-section. By minimizing this function an optimum design can be obtained. The limit between acceptable and unasceptable designs is governed by side and behaviour constraints. Side constraints are basically limits on the design variables. They are prescribed to satisfy CPCI code recuirements, and /or to impose certain design conditions that the resulting crosssection be of a particular shape. The behaviour constraints are imposed to ensure the performance of the beam at service conditions at all load stages that may be critical during the life of the structure, as specified by the CPCI code, as well as to neet the strength requirements specified in the code.

The preceding constrained minimization problem is converted to a sequence of unconstrained minimization problem by using the penalty function method of Fiacco and McCornick Ref. 1), in order to be able to use one of the powerful unconstrained minimization method. In this work, the Fletcher and Powell minimization method, (Ref. 2), which is considered the most powerful unconstrained minimization method, is used. The resulting function, F(V) can be expressed as follows:

$$\mathbf{F}(\mathbf{V}) = \mathbf{C}(\mathbf{V}) + \mathbf{P}(\mathbf{V}) \tag{2}$$

where the penalty function, P(V) is given by,

$$P(V) = R. \sum_{j=1,2}^{4} 1/g_{j}(V)$$
 (3)

and $g_j(V) \ge 0$ is the jth constraint function j = 1,2,...,q and q is the total number of side and behaviour constraints. Also, R is an arbitrary constant greater than zero which represents the relative weight of the constrained functions in the F(V) function.

The minimization procedure outlined in this work has been implemented using a FORTRAN IV program. Numerous numerical results indicate that the present structural synthesis capability is an efficient and convenient way for selecting minimum cost design for prefabricated prestressed concnete beams of various shapes and subjected to different loading conditions. Results also indicate that due to the presence of relative minima in the design space, it is not necessary to chose a good initial design. That is, a relatively costly initial design does not affect the minimum cost obtained. In fact, for such cases the optimum design obtained may have less cost than that resulting from an initially good design, It is pointed out that the major reduction in the cost for all the cases considered occured after only one trial. As a result, an optimum design can be achieved after a relatively short computer-run time.

In the following, sample results are presented for a simply supported beam which is desired to be of an I shape with a limited depth of less than 25 in., starting with an initial design of a rectangular shape. The initial and the optimum design obtained are shown in figures (22, 2b), respectively. In table 1 the costs and operational informations are listed. It can be realized that a reduction of the cost from 24 \$ / ft. to 7.8 \$ / ft is achieved after only one trial, and that the other two computer runings have minor effect on the overall cost. It is noted that the optimum obtained is a constrained optimum, which is the case for all the other designs considered in this work.
